

(18.1) The blood volume of a patient is to be determined by means of  $^{32}\text{P}$ . For this purpose 15.0 ml of blood is withdrawn from the patient and mixed with a very small volume of  $\text{Na}_2\text{H}^{32}\text{PO}_4$  of high specific activity. In 1 h the erythrocytes (red blood cells) take up all the  $^{32}\text{P}$ ; 1 ml is found to have an activity of 216000 cpm in the detector system used. Exactly 5.00 ml of this tagged sample is injected into the patient, and 30 min later a new sample is withdrawn; 10 ml of this gives 2300 cpm. Calculate the blood volume.

First of all check if any corrections for radioactive decay are necessary:

$$t_{\text{half}} := 14.3 \cdot \text{day} \quad R_{\text{fac}} := 2^{\frac{30 \cdot \text{min}}{14.3 \cdot \text{day}}} \quad R_{\text{fac}} = 1.001 \quad Bq := \text{sec}^{-1} \quad \text{cpm} := \text{min}^{-1}$$

Hence 30 minutes make no practical difference and no corrections are really necessary. However, we will do it here anyway in order to show the method

Given in the text are:

$$S_0 := 216000 \cdot \text{cpm} \cdot \text{mL}^{-1} \quad v_0 := 5 \cdot \text{mL} \quad A := 2300 \cdot \text{cpm} \cdot R_{\text{fac}} \quad v_A := 10 \cdot \text{mL}$$

Next; calculate the specific activity of the blood:

$$S := \frac{A}{v_A} \quad S = 3.837 \cdot \frac{Bq}{\text{mL}}$$

Use:  $v_0 \cdot S_0 = (v_0 + V) \cdot S$  (a simple mass balance on activity) to compute the blood volume (neglect  $v_0$  in comparison with  $V$ )

$$V := \frac{v_0 \cdot S_0}{S} \quad V = 0.005 \cdot \text{m}^3 \quad V = 4.7 \cdot \text{liter}$$
